

# Online Scheduling of Bounded Length Jobs to Maximize Throughput

Christoph Dürr (F-Paris)    Nguyen Kim Thang (F-Evry)  
Łukasz Jeż (PL-Wrocław)

September 23, 2011

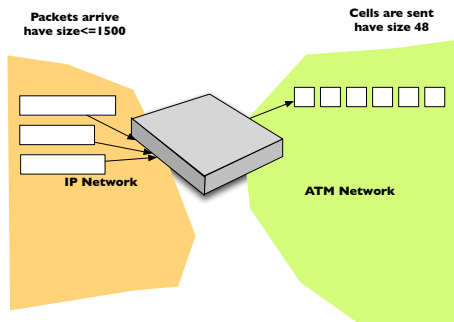

# The problem

- ▶ Every time slot a new product is produced
- ▶ It cannot be stored, must be immediately delivered
- ▶ Customers arrive on-line. Customer  $i$  arrives at time  $r_i$ , and promises to pay  $w_i$  Euros if he gets  $p_i$  units before deadline  $d_i$  (all integers)
- ▶ Goal: maximize revenue

## A network motivation

- ▶ Consider a gateway between an TCP/IP network and an ATM network
- ▶ IP packets arrive ( $r_i$ ) with a weight ( $w_i=QoS$ ), a deadline ( $d_i$ ) and a length ( $p_i \leq 1500$ )
- ▶ ATM cells have fixed small size (48)
- ▶ IP packets that want to transite over the ATM network split into unit size cells.
- ▶ Goal: maximize total weight of packets sent on-time

# A scheduling problem $1|online-r_i; pmtn| \sum w_i(1 - U_i)$

- ▶ A single machine
- ▶ Jobs arrive on-line at release times
- ▶ One has to find a preemptive schedule which maximizes total weight of jobs completed on-time
- ▶ The competitive ratio of an algorithm  $A$  is  $\max_I OPT(I)/A(I)$ , over all instances  $I$
- ▶ The competitive ratio of the problem is  $\min_A \text{ratio}(A)$ , over all on-line algorithms  $A$

# What is known?

## General model

- ▶ Randomized ratio is unbounded [Koren,Shasha'94]
- ▶ For  $p_i \leq k$ , the deterministic ratio is  $\Theta(k/\log k)$ .
- ▶ For  $p_i = k$ , the deterministic ratio is at most 5

## model $w_i = p_i$ (maximize processor usage)

- ▶ offline problem is NP-hard [bin packing]
- ▶ deterministic ratio is 4 [Lawler'90],[Baruah..'94]

## unweighted model $w_i = 1$

- ▶ offline problem is polynomial [Lawler'90]
- ▶ randomized ratio is at most 130000 [Kalyanasundaram,Pruhs'03]
- ▶ For  $p_i \leq k$ , deterministic ratio is  $\Omega(\log k / \log \log k)$  and  $O(\log k)$

For the unweighted case deterministic ratio is  $O(\log k)$

### Available job

Job  $j$  is available for the algorithm at time  $t$ , if  $j$  is not completed, and  $d_j - t$  does not exceed remaining work for  $j$ .

SHORTEST REMAINING PROCESSING TIME (SRPT) is the online algorithm which executes always the available job with smallest remaining work.

Let  $k = \max p_j$ , and  $H_k := 1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{k}$ .

### Theorem

SRPT is  $2H_k$ -competitif.

# A charging scheme

- ▶ Fix arbitrary instance. Consider schedules produced both by algorithm and by adversary.
- ▶ We denote the  $p_j$  units of a job by  $(j, p_j), \dots, (j, 2), (j, 1)$  where in  $(j, b)$ ,  $b$  stands for remaining work at moment of execution.
- ▶ Every unit  $(j, b)$  scheduled by the adversary is charged  $1/p_j$  to some job scheduled by the algorithm.
- ▶ Every job scheduled by the algorithm will get at most  $2H_k$  charges in total.

# Crucial observations

If SRPT schedules  $(i, a)$  at time  $t$ ,

1. then if  $a > 1$ , at time  $t + 1$  SRPT will schedule some  $(i', a')$  with  $a' < a$  since  $(i, a - 1)$  is candidate.
2. SRPT will complete some job between  $t$  and  $t + a$ .

# Type of charges

Let  $(j, b)$  be a unit scheduled by adversary at time  $t$ .

Let  $(i', a)$  the unit scheduled by algorithm at the same time.

We call  $1/a$  the *capacity* of this unit.

1. if the capacity is sufficient, we charge  $(j, b)$  to the next job completed by the algorithm from  $t$  on.
2. is insufficient or algorithm is *idle*, then let  $s$  be the last moment when  $j$  was available for the algorithm. We charge  $(j, b)$  to the next job completed by the algorithm from  $t$  on.

## Bound type 1 charges

- ▶ Let  $i$  be a job completed by the algorithm at time  $t$ .
- ▶ Let  $s$  be the smallest time such that  $[s, t]$  has no idle time, nor completions except  $i$ .
- ▶  $i$  receives all type 1 charges through units in  $[s, t)$ .
- ▶  $i$  receives at most  $1/a$  through  $(i', a)$ .
- ▶ the capacities of units in  $[s, t)$  are strictly decreasing.
- ▶ Therefore  $t - s \leq k$ , and the total type 1 charge is at most  $H_k$ .

## Bound type 2 charges

- ▶ Let  $i$  be a job completed by the algorithm at time  $t$ .
- ▶ Let  $J$  be the set of units type 2 charged to  $i$ .
- ▶ Every  $(j, b) \in J$  is scheduled not before  $t$
- ▶ Key observation: The  $\ell$ -th unit  $(j, b) \in J$  satisfies  $d_j \geq t + \ell$ , and therefore  $p_j \geq \ell$  since at  $t$   $j$  is not available anymore.
- ▶ So

$$\sum_{(j,b) \in J} \frac{1}{p_j} \leq \sum_{\ell=1}^k \frac{1}{\ell} = H_k.$$

## general model ( $w_j$ arbitrary)

- ▶ No deterministic algorithm is better than  $k/\ln k$ -competitif.
- ▶ Schedule the available job  $j$  which maximizes the *Smith*-ratio  $w_j/q_j$ , where  $q_j$  is the remaining work  $j$ . This is  $O(k)$ -competitif.
- ▶ There is a more subtle algorithm with ratio  $O(k/\ln k)$  where the hidden constant converges to 1 when  $k$  goes to  $\infty$ .

# Summary

	<i>offline</i>	<i>randomized</i>	<i>deterministic</i>
general model		unbounded	
bounded proc. time	[knapsack]	$O(\log k)$ $\Omega(\sqrt{\log k / \log \log k})$	$O(k / \log k)$ $\Omega(k / \log k)$
bounded proc. time	$O(n^4)$	$\leq 130000$	$O(\log k)$ $\Omega(\log k / \log \log k)$
unit weight			
equal proc. time	$O(n^4)$		$\in [2.598, 5]$
equal proc. time	$O(n \log n)$		$\rightarrow 1$
unit weight			
unit proc. time	[matching]		$\in [1.618, 1.83]$
